

PHYS 260: Relativity and Modern Physics

William Homier¹

¹*McGill University Physics, 3600 Rue University, Montréal, QC H3A 2T8, Canada*

December 1, 2025

Abstract

This course covers the history and foundations of special relativity, including Lorentz transformations in both kinematics and dynamics, as well as the transformation of electric and magnetic forces. In the modern physics portion, the course introduces foundational concepts of quantum mechanics, beginning with probability theory, followed by the Schrödinger equation, the Heisenberg uncertainty principle, the Born rule, and applications such as quantum scattering and tunneling. The course consists of three hours of lectures per week in the Fall term. Prerequisite: CEGEP physics or PHYS 142. Corequisite: MATH 222.

1 Introduction

My personal opinion for this course is that it is very interesting, and I really enjoyed learning about both special relativity and modern physics. The concepts are quite different from classical mechanics, and they challenge our intuition about how the universe works. Overall, I found the course to be engaging and thought-provoking.

2 Prerequisite knowledge

2.1 Dimensional analysis

Dimensional analysis is a method used in physics and engineering to analyze the relationships between different physical quantities by identifying their fundamental dimensions (such as length, mass, time, etc.). It helps to ensure that equations are dimensionally consistent and can be used to derive relationships between variables.

Theorem 1. (Principle of Dimensional Homogeneity) *Whenever we have an equation of the form (... something ...) = (... something else ...) then "something" and "something else" must have the same dimensions.*

Corollary 1.1. *A physical law must be independent of the units in which it is expressed.*

Corollary 1.2. *A physical law can always be expressed in a non-dimensional form.*

Theorem 2. (Buckingham Pi Theorem) *Given n relevant variables with r fundamental dimensions, $n - r$ dimensionless groupings of the variables can be found.*

Problem 1

2.2 Complex variables

A complex variable is a variable that can take on complex values, which are numbers that have both a real part and an imaginary part. Complex variables are often used in mathematics and physics to represent quantities that have both magnitude and direction, such as electric fields or wave functions.

Theorem 3 (Euler's Formula). *For any real number x ,*

$$e^{ix} = \cos(x) + i \sin(x)$$

Definition 1. *The complex conjugate of a complex number $z = a + bi$ is given by $z^* = a - bi$.*

Definition 2. *The modulus (or absolute value) of a complex number $z = a + bi$ is given by $|z| = \sqrt{a^2 + b^2}$.*

Definition 3. The polar form of a complex number $z = a + bi$ is given by $z = r(\cos \theta + i \sin \theta)$, where $r = |z|$ and $\theta = \tan^{-1}(b/a)$.

Theorem 4 (De Moivre's Theorem). For any real number x and integer n ,

$$(\cos(x) + i \sin(x))^n = \cos(nx) + i \sin(nx)$$

Definition 4. Some useful complex identities include:

- $e^{i\pi} + 1 = 0$
- $\cos(x) = \frac{e^{ix} + e^{-ix}}{2}$
- $\sin(x) = \frac{e^{ix} - e^{-ix}}{2i}$

2.3 Trigonometric identities

Some useful trigonometric identities include:

- Pythagorean identity: $\sin^2(x) + \cos^2(x) = 1$
- Angle sum and difference identities:
 - $\sin(a \pm b) = \sin(a) \cos(b) \pm \cos(a) \sin(b)$
 - $\cos(a \pm b) = \cos(a) \cos(b) \mp \sin(a) \sin(b)$
- Double angle identities:
 - $\sin(2x) = 2 \sin(x) \cos(x)$
 - $\cos(2x) = \cos^2(x) - \sin^2(x) = 2 \cos^2(x) - 1 = 1 - 2 \sin^2(x)$
- Half angle identities:
 - $\sin^2\left(\frac{x}{2}\right) = \frac{1 - \cos(x)}{2}$
 - $\cos^2\left(\frac{x}{2}\right) = \frac{1 + \cos(x)}{2}$
 - $\cos^2(x) = \frac{1 + \cos(2x)}{2}$
 - $\sin^2(x) = \frac{1 - \cos(2x)}{2}$

3 Special Relativity

Special relativity is a theory of physics that describes the behavior of objects moving at high speeds, particularly those approaching the speed of light. It was developed by Albert Einstein in 1905 and is based on two postulates: the laws of physics are the same for all observers in uniform motion relative to one another, and the speed of light in a vacuum is constant and independent of the motion of the source or observer. Special relativity has many important implications, including time dilation, length contraction, and the equivalence of mass and energy (as expressed in the famous equation $E = mc^2$). It has been confirmed by numerous experiments and is a fundamental part of modern physics.

3.1 Spacetime

Definition 5 (Spacetime). *A four dimensional structure with space and time as coordinates.*

3.1.1 Galilean Geometry

Classical physics uses separate space and time. Frames S and S' with relative speed v along x satisfy

$$x' = x - vt, \quad y' = y, \quad z' = z, \quad t' = t.$$

$$\begin{pmatrix} x' \\ y' \\ z' \\ t' \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & -v \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ t \end{pmatrix}.$$

Velocity rule:

$$u'_x = u_x - v, \quad u'_y = u_y, \quad u'_z = u_z.$$

3.1.2 Lorentzian Geometry

Relativity uses a metric that mixes space and time. For events separated by $(\Delta t, \Delta x, \Delta y, \Delta z)$ the invariant interval is

$$s^2 = c^2 \Delta t^2 - \Delta x^2 - \Delta y^2 - \Delta z^2.$$

All inertial observers agree on s^2 .

3.1.3 4D Physics Basics

Definition 6 (Event). *A location and a time.*

Definition 7 (Reference Frame). *A coordinate system for events.*

Definition 8 (Inertial Reference Frame). *A frame where free objects keep constant momentum.*

Definition 9 (The Principle of Relativity). *All inertial frames use the same physical laws.*

3.2 Consequences of Interval Invariance

Definition 10 (Lorentz Factor).

$$\gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}}$$

with $\gamma > 1$.

Time dilation follows directly from the invariant interval. For motion at speed v ,

$$\Delta t = \gamma \Delta \tau.$$

Definition 11 (Proper Time). *Time measured in the frame where the object is at rest ($\Delta x = 0$).*

Length contraction comes from the same invariant relation:

$$L = L_0 \sqrt{1 - \frac{v^2}{c^2}} = \frac{L_0}{\gamma}.$$

Definition 12 (Proper Length). *Length measured in the frame where the object is at rest.*

Length contraction is geometric. Nothing physically compresses the material; different frames slice spacetime differently.

3.2.1 Relativity of Simultaneity

Two events are simultaneous in a frame when $\Delta t = 0$. Because

$$(\Delta s)^2 = c^2 \Delta t^2 - \Delta x^2 - \Delta y^2 - \Delta z^2$$

is invariant, setting $\Delta t = 0$ in one frame implies $\Delta t' \neq 0$ in another. Simultaneity depends on the observer.

3.2.2 Geometric Units

Define time in meters through $t_{\text{geom}} = ct$. Light travels one meter of space in one meter of time. Velocities become

$$v_{\text{geom}} = \frac{x}{t_{\text{geom}}} = \frac{v}{c}.$$

In these units the Lorentz factor simplifies to

$$\gamma = \frac{1}{\sqrt{1 - v^2}}.$$

4.19 Transforming Maxwell's Equations

4.19.1 Doppler Shift and Wave Transformations

Consider the dispersion relation $\omega = ck$ for electromagnetic waves. Let us examine how a plane wave transforms when boosting to a frame moving with velocity v .

Given a plane wave:

$$\begin{aligned}\vec{E} &= E_0 \sin(kx - \omega t) \hat{y} \\ \vec{B} &= \left(\frac{E_0}{c}\right) \sin(kx - \omega t) \hat{z}\end{aligned}$$

Using the transformation law $E'_y = \gamma(E_y - vB_z)$, we obtain:

$$E'_y = \gamma E_0 \sin(kx - \omega t) (1 - v/c)$$

Since $\gamma(1 - v/c) = \sqrt{\frac{1-v/c}{1+v/c}}$, we have:

$$E'_y = E_0 \sqrt{\frac{1-v/c}{1+v/c}} \sin(kx - \omega t)$$

To express this entirely in primed coordinates, we use the inverse Lorentz transformations:

$$kx - \omega t = \sqrt{\frac{1-v/c}{1+v/c}} (k'x' - \omega't')$$

This yields the relativistic Doppler shift relations:

$$\begin{aligned}k' &= \sqrt{\frac{1-v/c}{1+v/c}} k \\ \omega' &= \sqrt{\frac{1-v/c}{1+v/c}} \omega\end{aligned}$$

Therefore, the transformed wave becomes:

$$E'_y = E_0 \sqrt{\frac{1-v/c}{1+v/c}} \sin(k'x' - \omega't')$$

Importantly, the phase velocity remains invariant: $\omega'/k' = \omega/k = c$. This confirms that the speed of light is the same in all reference frames, consistent with special relativity and Maxwell's equations.

The amplitude decreases according to $E_0 \sqrt{\frac{1-v/c}{1+v/c}}$, which reflects the frame-dependence of energy. Notably, there is no reference frame in which an electromagnetic wave appears frozen (i.e., non-oscillating). Maxwell's equations do not admit static solutions for light waves. You can, of course, create standing waves in electromagnetism by taking a superposition of different waves, but these waves would still oscillate. This is a fundamental consequence of Maxwell's equations respecting the invariance of the speed of light across all inertial frames.

4.19.2 The Faraday Tensor

In the previous section, we demonstrated how the electric and magnetic fields transform under a boost in the $+x$ direction. The key observation is that field components parallel to the boost direction remain invariant for both \vec{E} and \vec{B} , while perpendicular components transform according to:

$$\begin{aligned}\vec{E}'_{\perp} &= \gamma(\vec{E}_{\perp} + \mathbf{v} \times \vec{B}_{\perp}) \\ \vec{B}'_{\perp} &= \gamma\left(\vec{B}_{\perp} - \frac{\mathbf{v}}{c^2} \times \vec{E}_{\perp}\right)\end{aligned}$$

These equations resemble Lorentz transformations but differ fundamentally due to the cross products and mixing of spatial components from different fields. Since \vec{E} and \vec{B} together contain six independent components, they cannot form a four-vector, which has only four components. To properly describe these fields, we use the **Faraday tensor** (or field strength tensor), denoted $F^{\mu\nu}$:

$$F^{\mu\nu} = \begin{pmatrix} 0 & E_x/c & E_y/c & E_z/c \\ -E_x/c & 0 & B_z & -B_y \\ -E_y/c & -B_z & 0 & B_x \\ -E_z/c & B_y & -B_x & 0 \end{pmatrix}$$

This is an antisymmetric rank-2 tensor with two indices. While four-vectors are rank-1 tensors transforming as $X'^{\mu} = \Lambda^{\mu}_{\nu} X^{\nu}$, a rank-2 tensor transforms as:

$$F'^{\mu\nu} = \Lambda^{\mu}_{\alpha} \Lambda^{\nu}_{\beta} F^{\alpha\beta}$$

In matrix form: $F' = \Lambda F \Lambda^T$, where Λ is the Lorentz transformation matrix (for example of a lorentz transformation matrix check ??)

4.19.3 Maxwell's Equations in Tensor Form

The electromagnetic field is completely described by two tensors: the Faraday tensor $F^{\mu\nu}$ introduced above, and its dual $G^{\mu\nu}$, which exchanges the roles of electric and magnetic fields:

$$G^{\mu\nu} = \begin{pmatrix} 0 & B_x & B_y & B_z \\ -B_x & 0 & -E_z/c & E_y/c \\ -B_y & E_z/c & 0 & -E_x/c \\ -B_z & -E_y/c & E_x/c & 0 \end{pmatrix}$$

Maxwell's four equations can be elegantly written as:

$$\begin{aligned}\partial_{\nu} F^{\mu\nu} &= \mu_0 J^{\mu} \\ \partial_{\nu} G^{\mu\nu} &= 0\end{aligned}$$

where $\partial_{\alpha} = \frac{\partial}{\partial x^{\alpha}}$ denotes the four-derivative, and J^{μ} is the four-current:

$$J^{\mu} = \begin{pmatrix} c\rho \\ \rho v_x \\ \rho v_y \\ \rho v_z \end{pmatrix}$$

Generalization to Curved Spacetime: In general relativity, where spacetime is curved, Maxwell's equations retain their form with one modification: ordinary derivatives are replaced by covariant derivatives ∇_α :

$$\begin{aligned}\nabla_\nu F^{\mu\nu} &= \mu_0 J^\mu \\ \nabla_\nu G^{\mu\nu} &= 0\end{aligned}$$

The covariant derivative is defined as:

$$\nabla_\alpha V^\beta = \partial_\alpha V^\beta + \Gamma_{\alpha\eta}^\beta V^\eta$$

Here, $\Gamma_{\alpha\eta}^\beta$ are Christoffel symbols encoding the spacetime curvature. These symbols act as corrections that stitch together small flat patches of spacetime, allowing us to consistently define derivatives on a curved manifold. The remarkable similarity between special and general relativistic forms reflects the equivalence principle.

Definition 13 (Equivalence Principle). *Locally, in a small patch of spacetime, the laws of physics take on their special relativistic forms (e.g., their flat spacetime forms).*

Any curved spacetime appears flat, so Maxwell's equations maintain their structure. This is analogous to how Earth appears flat to us when we stand on its surface—at small scales, the curvature is imperceptible, and we perceive a locally flat geometry. Similarly, in a small enough region of curved spacetime, the effects of gravity vanish and spacetime looks like flat Minkowski space. The Christoffel symbols vanish in these infinitesimal flat patches, and the covariant derivative reduces to the ordinary derivative.

Exercise: Pick two of the transformation laws that we have previously derived (maybe one of the parallel and one of the perpendicular ones). Show explicitly that by Lorentz transforming the Faraday tensor, we recover the transformation laws. Note: this is a tricky thing to do if you are rusty with your index manipulations so I recommend budgeting some time for this, even if you only have time to do a cursory job before lecture you can come back to it later on while studying for the final.

5 Answer Key

Problem 1

6 Appendix

6.1 Different Lorentz transformation matrices for different boosts

A boost mixes only t with the coordinate of the boost. Perpendicular coordinates stay unchanged. For speed v , set $\beta = v/c$ and $\gamma = (1 - \beta^2)^{-1/2}$.

Boost in $+x$:

$$\Lambda_{+x} = \begin{pmatrix} \gamma & -\beta\gamma & 0 & 0 \\ -\beta\gamma & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Boost in $-x$:

$$\Lambda_{-x} = \begin{pmatrix} \gamma & +\beta\gamma & 0 & 0 \\ +\beta\gamma & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Boost in $+y$:

$$\Lambda_{+y} = \begin{pmatrix} \gamma & 0 & -\beta\gamma & 0 \\ 0 & 1 & 0 & 0 \\ -\beta\gamma & 0 & \gamma & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Boost in $-y$:

$$\Lambda_{-y} = \begin{pmatrix} \gamma & 0 & +\beta\gamma & 0 \\ 0 & 1 & 0 & 0 \\ +\beta\gamma & 0 & \gamma & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Boost in $+z$:

$$\Lambda_{+z} = \begin{pmatrix} \gamma & 0 & 0 & -\beta\gamma \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta\gamma & 0 & 0 & \gamma \end{pmatrix}$$

Boost in $-z$:

$$\Lambda_{-z} = \begin{pmatrix} \gamma & 0 & 0 & +\beta\gamma \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ +\beta\gamma & 0 & 0 & \gamma \end{pmatrix}$$
